

Creating First EC2 Instance using Terraform

To Begin with the Lab

Summary of the Lab

This lecture demonstrates how to create and manage an AWS EC2 instance using Terraform. The process includes defining the AWS provider and instance configuration, initializing Terraform with `terraform init`, reviewing changes using `terraform plan`, deploying resources with `terraform apply`, and removing them with `terraform destroy`. Planning helps validate changes before deployment.

- Terraform AWS EC2 Instance – Quick Steps
- Create Terraform Configuration (.tf)
- Define AWS provider (region, access key, secret key).
- Define EC2 instance resource (AMI ID, instance type, name).
- Initialize Terraform

```
terraform init
```

- Downloads required providers and initializes the project.
- Preview Changes

```
terraform plan
```

- Shows what Terraform will create, change, or destroy.
- Save a Plan (Optional)

```
terraform plan -out myplan.out
```

- Saves the execution plan to a file.
- Create Resources

```
terraform apply
```

- or

```
terraform apply myplan.out
```

- Creates the EC2 instance on AWS.
- Destroy Resources

```
terraform destroy
```

- Deletes the created infrastructure.
